Bipolar Membrane Electrodialysis Unit

CO₂ from seawater

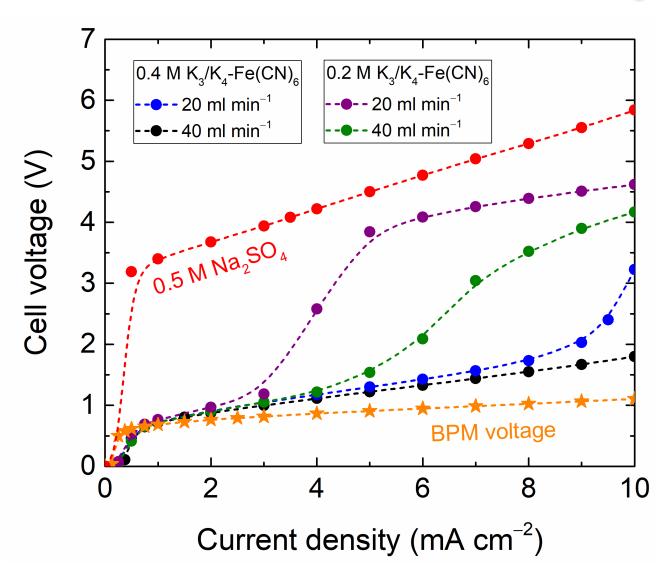

- CO₂ in the atmosphere is in constant equilibrium with the ocean.
- World's ocean represents a natural carbon sink that absorbs 25% of CO₂ entering the atmosphere.
- More than 98% of CO₂ of the carbon atmosphere-ocean system is stored in the oceans as dissolved inorganic carbon (DIC).
- The effective concentration of CO₂ in seawater is a factor of 128 times larger than in the air.

Key performances

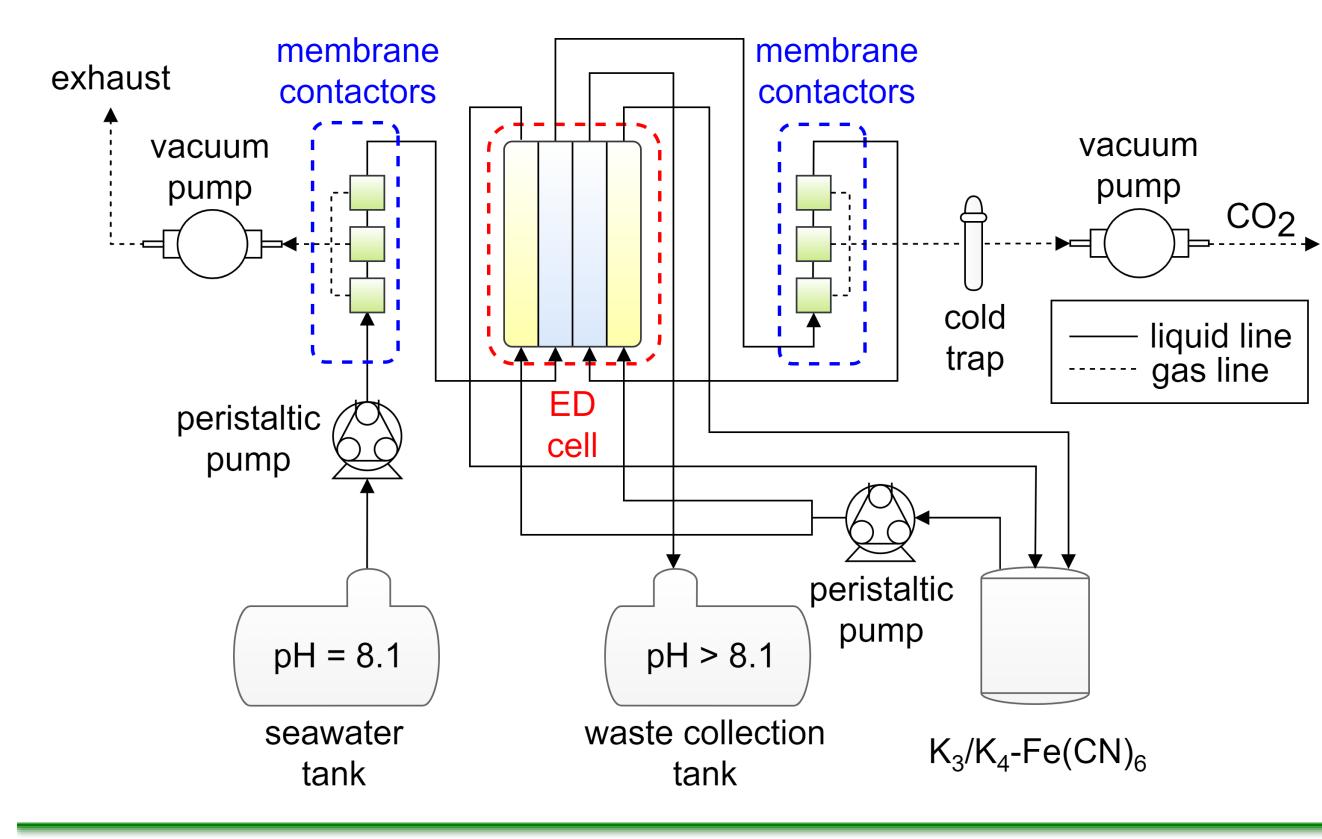

- Direct coupling of electrochemical CO₂ extraction and conversion by using a bipolar membrane (BPM) electrodialysis cell and a vapor-fed CO₂ reduction cell.
- Record low electrochemical energy consumption of 0.98 kWh kg⁻¹ CO₂ or 155.4 kJ mol⁻¹ CO₂ from seawater.
- Record high CO₂ extraction efficiency of 71% of total DIC in seawater.
- Highly selective conversion of CO₂ with more than 70% into fuels and chemicals in the vapor-fed device.

Electrodialysis performance

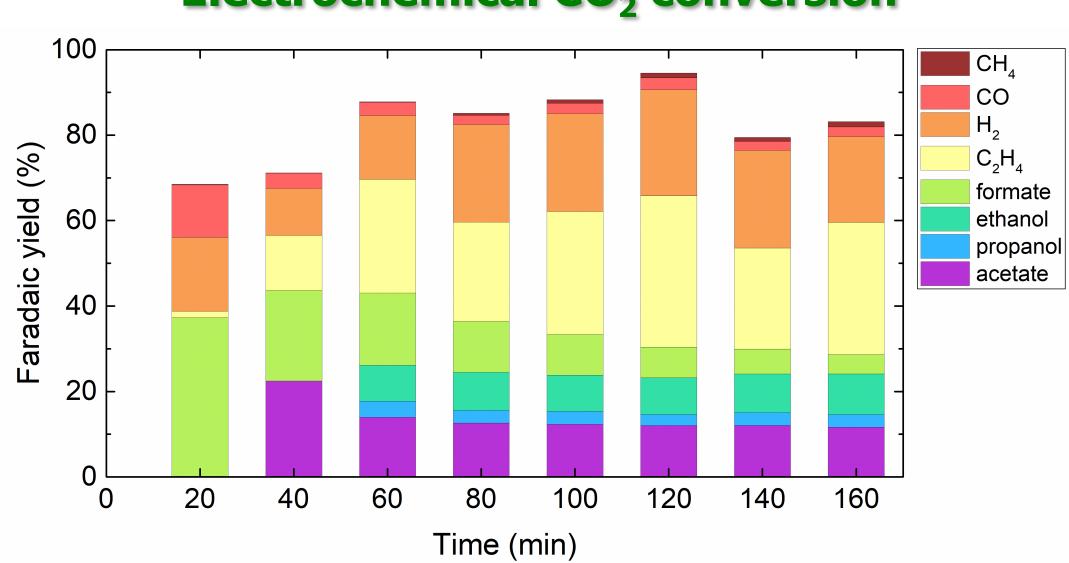

- Replacing the water splitting process at the electrodes with one-electron redox couple reactions, significantly reduced the cell voltage.
- At an optimum solution concentration and flow rate, the total cell voltage was close to the BPM voltage.
- The electrode reactions were limited by mass transport of the redox couple at low electrolyte concentrations and flow rates.

CO₂ capture process

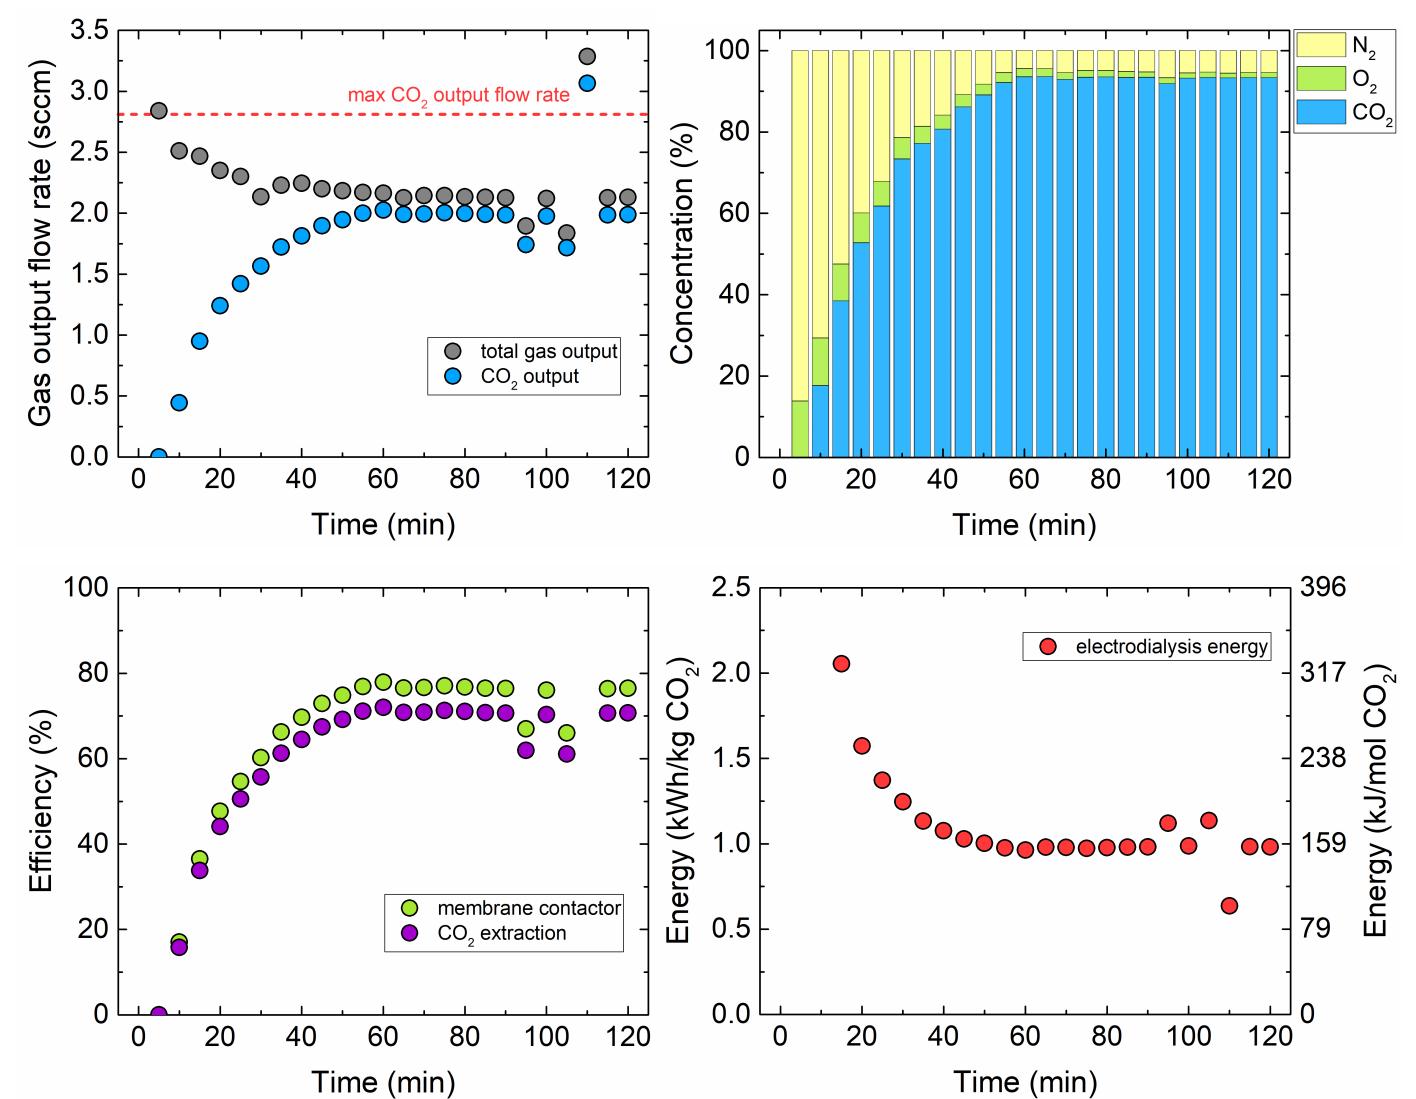

Electrochemical CO₂ conversion

- Extracted CO₂ from seawater was electrochemically converted in tandem oxygen reduction (O₂R) and CO₂ reduction (CO₂R) vapor fed cells.
- The O₂R cell used Ag catalyst on a gas diffusion electrode (GDE) to mitigate oxygen flow into the CO₂R cell.
- The CO₂R reaction in a vapor fed cell containing a Cu-GDE achieved selectivity as high as 73% of CO₂ converted to fuels and liquid products.

CO₂ extraction performance

- CO_2 with output flow rate of 2 sccm was extracted from seawater with an input seawater flow rate of 37 ml min⁻¹.
- The extracted gas was a mixture of CO_2 (93%), O_2 (1.5%) and N_2 (5.5%).
- The extraction efficiency (measured CO₂ output/DIC input) was 71% and the membrane contactor efficiency (measured CO₂ output/theoretical CO₂ output flow at the given pH and seawater flow rate) was 76%.
- Record electrodialysis energy of 0.98 kWh kg⁻¹ CO₂ or 155.4 kJ mol⁻¹ CO₂.

Conclusion

- Indirect seawater capture system using a BPM electrodialysis was constructed and yielded 71% CO₂ extraction efficiency and 155.4 kJ mol⁻¹ CO₂.
- A total Faradaic yield of 93% was attained using tandem pre-O₂R and CO₂R vapor fed cells.
- The proof-of concept system provides a unique technological pathway for CO₂ capture and conversion using electrochemical processes only.
